

Homework 4  
Due on Monday, December 02, 2024.

**Problem 1:** *Stability function adjoint methods.* Consider an  $s$ -stage RK method with stability function  $\psi(z)$ . Show that its adjoint method has stability function  $1/\psi(-z)$ .

**Problem 2:** *Implementing implicit midpoint.* Consider the Runge–Kutta method expressed by the Butcher Tableau

$$\begin{array}{c|c} \frac{1}{2} & \frac{1}{2} \\ \hline & 1 \end{array}$$

(a) Show that the method can be equivalently expressed as

$$y_{n+1} = y_n + hf\left(t_n + \frac{h}{2}, \frac{1}{2}(y_n + y_{n+1})\right)$$

(b) Let

$$G(y) = y - y_n - hf\left(t_n + \frac{h}{2}, \frac{1}{2}(y_n + y)\right).$$

Show that the Newton iteration for finding a root of  $G$  is

$$y \leftarrow y - \left(I - \frac{h}{2}f_y\left(t_n + \frac{h}{2}, \frac{1}{2}(y_n + y)\right)\right)^{-1}G(y),$$

where

$$f_y(t, y) = \frac{\partial f}{\partial y}(t, y).$$

(c) Consider the ODE

$$y' = -100(y - \sin(t)), \quad y(0) = 1$$

for  $t \in [0, 3]$ . Implement the midpoint method in Python.

**Problem 3: Implementing Gauss–Legendre.** Consider the Runge–Kutta method expressed by the Butcher Tableau

$$\begin{array}{c|cc} \frac{1}{2} - \frac{\sqrt{3}}{6} & \frac{1}{4} & \frac{1}{4} - \frac{\sqrt{3}}{6} \\ \frac{1}{2} + \frac{\sqrt{3}}{6} & \frac{1}{4} + \frac{\sqrt{3}}{6} & \frac{1}{4} \\ \hline & \frac{1}{2} & \frac{1}{2} \end{array}$$

(a) Show that the method can be equivalently expressed as

$$\begin{aligned} k_{n+1/3} &= f\left(t_n + \left(\frac{1}{2} - \frac{\sqrt{3}}{6}\right)h, y_n + \frac{1}{4}hk_{n+1/3} + \left(\frac{1}{4} - \frac{\sqrt{3}}{6}\right)hk_{n+2/3}\right) \\ k_{n+2/3} &= f\left(t_n + \left(\frac{1}{2} + \frac{\sqrt{3}}{6}\right)h, y_n + \left(\frac{1}{4} + \frac{\sqrt{3}}{6}\right)hk_{n+1/3} + \frac{1}{4}hk_{n+2/3}\right) \\ y_{n+1} &= y_n + \frac{h}{2}(k_{n+1/3} + k_{n+2/3}). \end{aligned}$$

(b) Show that the method can be equivalently expressed as

$$\begin{aligned} \underbrace{\begin{bmatrix} y_{n+1/3} \\ y_{n+2/3} \end{bmatrix}}_{=\vec{y}} &= y_n \mathbf{1} + h \underbrace{\begin{bmatrix} \frac{1}{4} & \frac{1}{4} - \frac{\sqrt{3}}{6} \\ \frac{1}{4} + \frac{\sqrt{3}}{6} & \frac{1}{4} \end{bmatrix}}_{=M} \underbrace{\begin{bmatrix} f\left(t_n + \left(\frac{1}{2} - \frac{\sqrt{3}}{6}\right)h, y_{n+1/3}\right) \\ f\left(t_n + \left(\frac{1}{2} + \frac{\sqrt{3}}{6}\right)h, y_{n+2/3}\right) \end{bmatrix}}_{=F(\vec{y})} \\ y_{n+1} &= y_n + \frac{h}{2} \mathbf{1}^\top F(\vec{y}). \end{aligned}$$

(c) Let

$$G(\vec{y}) = \vec{y} - y_n \mathbf{1} - hMF(\vec{y}).$$

Show that the Newton iteration for finding a root of  $G$  is

$$\vec{y} \leftarrow \vec{y} - \left( I - hM \begin{bmatrix} f_y\left(t_n + \left(\frac{1}{2} - \frac{\sqrt{3}}{6}\right)h, y_{n+1/3}\right) & 0 \\ 0 & f_y\left(t_n + \left(\frac{1}{2} + \frac{\sqrt{3}}{6}\right)h, y_{n+2/3}\right) \end{bmatrix} \right)^{-1} G(\vec{y}),$$

where

$$f_y(t, y) = \frac{\partial f}{\partial y}(t, y).$$

(d) Consider the ODE

$$y' = -100(y - \sin(t)), \quad y(0) = 1$$

for  $t \in [0, 3]$ . Implement the Gauss–Legendre method in Python.

**Problem 4: Cost of Newton for implicit RK.** Consider a fully implicit  $s$ -stage RK method with Butcher tableau

$$\begin{array}{c|cccc} c_1 & a_{11} & a_{12} & \dots & a_{1s} \\ c_2 & a_{21} & a_{22} & \dots & a_{2s} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ c_s & a_{s1} & a_{s2} & \dots & a_{ss} \\ \hline & b_1 & b_2 & \dots & b_s \end{array}$$

applied to  $y' = f(t, y)$ , where  $y \in \mathbb{R}^d$ .

- Show that  $y_n \mapsto y_{n+1}$  can be obtained by solving a  $(sd)$ -dimensional root-finding problem.
- Show that Newton's iteration for finding such a root requires inverting  $(sd) \times (sd)$  matrices. (Therefore, if  $K$  Newton steps are required, the cost is  $\mathcal{O}(Ks^3d^3)$  flops.)

**Problem 5: Diagonally implicit RK method.** A Diagonally Implicit RK (DIRK) method is an RK method with a lower triangular Butcher tableau

$$\begin{array}{c|cccc} c_1 & a_{11} & 0 & \dots & 0 \\ c_2 & a_{21} & a_{22} & \dots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ c_s & a_{s1} & a_{s2} & \dots & a_{ss} \\ \hline & b_1 & b_2 & \dots & b_s \end{array}$$

(Recall that explicit RK methods have *strictly* lower triangular Butcher tableaux.) Consider the DIRK method applied to  $y' = f(t, y)$ , where  $y \in \mathbb{R}^d$ .

- Show that  $y_n \mapsto y_{n+1}$  can be obtained by solving  $s$  separate  $d$ -dimensional root-finding problems.
- Show that Newton's iteration for finding such roots requires inverting  $d \times d$  matrices. (Therefore, if  $K$  Newton steps are required for each of the  $s$  stages, the cost is  $\mathcal{O}(Ksd^3)$  flops.)
- Consider the ODE

$$y' = -100(y - \sin(t)), \quad y(0) = 1$$

for  $t \in [0, 3]$ . Implement the DIRK method

$$\begin{array}{c|ccc} x & x & 0 & 0 \\ \frac{1+x}{2} & \frac{1-x}{2} & x & 0 \\ 1 & -3x^2/2 + 4x - 1/4 & 3x^2/2 - 5x + 5/4 & x \\ \hline & -3x^2/2 + 4x - 1/4 & 3x^2/2 - 5x + 5/4 & x \end{array}$$

with  $x = 0.4358665215$ . (The  $x = 0.4358665215$  is a root of the polynomial  $6x^3 - 18x^2 + 9x - 1$ .)

*Remark.* It can be shown that DIRK methods have an order barrier of  $p \leq s + 1$ .

**Problem 6:** *Splitting method for a simple pendulum.* Consider the ODE

$$\begin{aligned}q' &= \frac{p}{mL^2} & q(0) &= 0 \in \mathbb{R} \\p' &= -mgL \sin q & p(0) &= 1 \in \mathbb{R}\end{aligned}$$

for  $t \in [0, 10]$ . This is the Hamiltonian dynamics of a simple pendulum with angle  $q$  from the vertical (in radians), angular momentum  $p = mL^2 q'$ , mass  $m$ , (rigid) string length  $L$ , and gravitational acceleration  $g = 9.81$ . For simplicity, set  $m = 1$  and  $L = 1$ . Consider the splitting

$$\frac{d}{dt} \begin{bmatrix} q \\ p \end{bmatrix} = \begin{bmatrix} \frac{p}{mL^2} \\ 0 \end{bmatrix} + \begin{bmatrix} 0 \\ -mgL \sin q \end{bmatrix}.$$

Implement the Lie–Trotter and Strang splitting methods.

**Problem 7:** *Baker–Campbell–Hausdorff formula.* Consider the linear ODE

$$y' = \underbrace{(B + C)}_{=A} y, \quad y(0) = y_0.$$

Consider using the Lie–Trotter splitting method, and consider the local error  $e^{hA}y_0 - e^{hC}e^{hB}y_0$ . Show

$$e^{hA} - e^{hC}e^{hB} = \frac{h^2}{2}[B, C] + \mathcal{O}(h^3),$$

where  $[B, C] = BC - CB$  is the *commutator* of the matrices  $B$  and  $C$ .
